Non-Performing Debts in Chinese Enterprises
Patterns, Causes, and Implications for Banking Reform*

Abstract

Given the domination of bank financing, non-performing debts (NPDs) in large Chinese enterprises are a proxy for non-performing loans (NPLs) in China's major banks. Using the firm-level survey of more than 20,000 large and medium-sized industrial enterprises by the National Bureau of Statistics of China, this paper estimates both the level and ratio of NPDs across ownership, industry, and region during 1995-2002. The results show NPD ratios have been falling due to both rapid expansion of better performing non-state enterprises (NSE) and improving performance of the state-owned enterprises (SOEs). However, SOEs are still much more likely to generate NPDs than NSEs. The paper provides useful tools and sector information for assessing enterprise debt risks and draws lessons for banking reform in China.

This paper is prepared for presentation at the Asian Economic Panel meeting in Hong Kong, 12-13 April 2004.

The author is also grateful to Wing Thye Woo, Dwight Perkins, Jeff Sachs, Alan Siu, and Richard Wong for encouragement, advice and help on the project. The author will take responsibility for all the errors.

1. Introduction

In early 2004 the newly established China Banking Regulatory Commission (CBRC) announced that during 2003 the ratio of non-performing loans (NPLs) in China's banking institutions fell 4.69 percentage points to 15.19%, reducing NPLs by RMB157.4 billion to a level of RMB 2.4 trillion. Outsiders took this news cautiously since they don't know how China's banks calculate their NPLs. Most analysts and commentators would still put China's NPL ratios at a much higher level than the official one, usually two to three times of the official NPL ratio but with little supporting information. The uncertainty on the true level of NPLs in China has been a major concern for policy-makers and investors. Most researchers have attempted to study China's NPLs using macro data since it is difficult to get reliable and representative micro data from the Chinese banks.

This paper provides an alternative approach to study the non-performing loans in China. Due to the limited development of stock markets and enterprises bond markets in China, banks are still the major holders of enterprises' long-term and short-term debts. Bank loans and enterprises debts can be regarded almost as the two sides of the same coin in China. The quality of loans depends heavily on the quality of enterprise debts given the dominance of bank financing on China's large and medium-sized enterprises. The quality of enterprise debts is directly linked to the profitability of the enterprises. The ability to pay the interest and principal of loans derives ultimately from profitability of the enterprises. This is especially true if we are examining groups of enterprises, where the variation in the timing and forms of cash flows should be averaged out, leaving the profitability as the most important aggregate measure on the quality of enterprise debts.

This paper uses the profitability conditions of the enterprises to measure and characterize the quality of enterprise debts. It uses both the reported profitability and the imputed profitability, which is based on the components of value added to give two alternative estimates on the quality of enterprise debts for various enterprise groups classified by ownership, industry, and region. The method is applied to a comprehensive annual enterprise survey of all the large and medium-sized industrial enterprises in China conducted by the National Bureau of Statistics of China. The information about the survey data can be found in Table A.1 to A.6 of the Data Appendix. As shown in Table A.6, the survey sample includes more than 20,000 enterprises and covers the period from 1995 to 2002. In 2002, the sample enterprises have 26 million employees, which is about 70.8% of China's industrial employment. They also incur RMB 5.7 trillion debts in 2002, which is as large as 43.6% of the total loans in China's financial institutions. In 2002, the sample enterprises contributed to about 19.2% of China's GDP. Clearly these enterprises are the most important leaders in the Chinese industrial sector. The aggregate financial information about the sample enterprises have been regularly reported in the Statistical Yearbook of China. The contribution of this paper is in using the disaggregated firm-level data to study the enterprise profitability and the quality of the enterprise debts. The paper derives both the level and ratio of non-performing enterprise debts across ownership, industry, and region for the period of 1995-2002. The results show that non-performing enterprise debts have indeed been falling due to both rapid expansion of better performing non-state enterprises and improvement in the performance of reforming state-owned enterprises (SOEs). This evidence is consistent with the findings of the CBRC on falling NPLs and NPL ratios in China's banking sector. However, the study also finds that the SOEs are still much more likely to generate NPDs than the non-state

enterprises (NSEs), providing a challenge as well as an opportunity for future banking reform. Based on the evolving pattern of enterprise profitability and the changing distribution of enterprise debts, the paper developed useful tools and sector information for managing enterprise debt risk as well as scenarios on how the NPDs in China may evolve in the future.

Section 2 defines the concepts of NPDs and NPD ratios used in this paper, which are based on the profitability conditions of the enterprises and the distribution of enterprise debts.

Section 3 shows the patterns of NPDs and NPD ratios across enterprise type, industry, and region.

Using the information derived in section 3, Section 4 examines the trend of NPD ratios during the period 1995-2002 and provides scenarios on the future of NPD ratios in China.

Section 5 examines the causes of NPDs and uses the logistic and linear regressions to identify the impact of various factors on the profitability of the enterprises.

Section 6 concludes the paper by discussing the implications of the statistical analysis in this paper on banking reform in China.

2. Defining and Estimating Non-Performing Debts

In recent years, the CBRC has been trying hard to monitor and supervise the NPLs in China's banking institutions. It developed detailed rules on the reporting of the amount of NPLs and NPL ratios. The purpose is to manage and reduce the financial risks by monitoring both the changing distribution of NPLs and the changing NPL ratios of individual banks and bank branches. This is clearly necessary and

useful. Poor governance at the banks is a sufficient condition for creating NPLs even when the enterprise sector is doing well.

However, the efforts by the CBRC and the individual banks in reducing NPLs are only necessary conditions. Ultimately, the quality of China's banking assets and enterprise debts depend directly on the profitability of China's enterprises. For example, in the short run it is easy for banks to reduce NPL ratios or even the amount of NPLs by simply expanding the total amount of loans. New loans are much less likely to have repayment problems in the short run but may create more bad loans in the future if they are extended to potentially loss-making enterprises. New loans can also help the existing loss-making enterprises to continue to pay their interest on old loans, also shifting the underlying risks to the future. These are the main reasons why the reliability of NPL statistics as reported by the banks can vary a lot depending on how they are calculated. No outsiders know well how the NPLs and NPL ratios in China's banks are actually calculated since the decisions on each individual case require judgments that are too much for outsiders to assess. This is why the analysts and commentators rely more on their study of China's macro economic conditions and sector performance to gauge the level of NPLs in China. Based on their personal impressions and understandings about the Chinese economy they report NPL ratios usually two to three times of the official one.

This paper attempts to develop an objective measure on the quality of enterprise debts in China. It uses the profitability as the only criteria in measuring the quality of debts. If the enterprises are making profits, the quality of their debts, more specifically their total liabilities, are regarded as performing. If making loss, their debts are non-performing. The amount of the NPDs for a group of enterprises are then the sum of the total liabilities in the loss-making enterprises in a specific group.

The NPD ratio for that group is simply sum of total liabilities in the loss-making enterprises divided by the sum of total liabilities in both the loss-making and profit-making enterprises in that group. This simple definition of NPD and NPD ratio makes our NPD statistics objective, easy to measure, and easy to understand.

Our concept of NPD ratio however is not applicable to an individual enterprise since an enterprise can either have performing or non-performing debts by our definition. In another word, in our definition, one enterprise cannot have 70% of their debts performing and 30% non-performing. For an individual enterprise, it may be making losses in the first few years but will make profits in the future. Its debt quality should be good after close examination by its creditors. Our definition of NPD would not be fair to this particular enterprise. On the other hand, we could also have a currently profitable enterprise which will become a loss-maker soon. Its debt quality would be bad upon close examination. Our assessment based only on current profitability may not do justice to this particular firm. However, these sort of enterprises should form a similar distribution across year, ownership, industry, and region. With a sizable group of enterprises by year, ownership, industry, and region, the variability in the timing of cash flows, profit-steams, payments to creditors, and others for each individual enterprises would offset each others, leaving the average NPD ratio for the group a much more reliable and accurate measure of the debt quality. This is why our concept of NPD ratio is useful only for measuring debt quality for groups of enterprises. In another word, the NPD statistics derived here are useful for understanding the macro or sector picture of the quality of enterprise debts in China. It is not designed to replace the detailed investigation on the quality of debts for specific projects and enterprises, usually carried out by commercial and investment banks. However, the study here would be very useful as a complementary

research to the policy-makers and practitioners since it provides the macro and sector performance benchmarks that are crucial for them to compare the performance of individual banks and enterprises with benchmark performance of the sector as a whole.

For our method to be useful, it needs to be applied to a representative sample with sizable groups of enterprises. The annual survey of large and medium-sized industrial enterprises by the National Bureau of Statistics happens to be a perfect data set for applying our method. The NBS data is in fact a census data, not really a sampling data, since it covers all large and medium-sized industrial enterprises population in China. In 2002, China has more than 180,000 industrial enterprises that have sales above RMB 5 million. The NBS sample only includes about 21,000 to 23,000 large and medium-sized industrial enterprises out of the 180,000. Many small industrial enterprises are not included in our study but most of them have limited access to external finance under current financial system in China.

It needs to be pointed out that enterprises included in the NBS survey each year are not the same group of enterprises. About 20% enterprises enter and exit the survey sample each year due to changes in their size classification or organizational changes such as mergers and acquisition, privatization, reorganization etc. This means that we are studying the largest and most dynamic frontier industrial enterprises in China. The sample cover enterprises in all industries, regions, and types of ownership such as SOEs, rural and urban collectives, private enterprises, domestic mixed ownership corporations, foreign invested enterprises, and enterprises with investment form Hong Kong, Macau, and Taiwan. It is entirely possible that the enterprises not included in our sample have worse performance than the enterprises in this NBS sample. In that case, the NPD ratios for the entire Chinese industrial sector would be

higher than reported in this study. Also, if the banks and non-industrial enterprises/projects in China are performing worse than the enterprises in this NBS sample, the overall NPD and NPLs situation for the Chinese economy as a whole would be worse than that for the sample enterprises revealed in this paper. Also, we cannot compare directly the NPL ratios reported by the CBRC and the NPD ratios estimated here since they are defined differently. The NPD ratios here are designed to examine the trend and the patterns on the quality of Chinese enterprise debts at the macro and sector level.

As shown in Table A.6, during the period from 1995 to 2002, the sample enterprises created about 60% to 70% of China's industrial employment and 33% to 43% of China's industrial value added. Most significantly, the sample enterprises contributed to about 14% to 19% of China's GDP. Their total liabilities, one of the key variables we examine in this paper, amount to about 45% to 65% of China's total banking loans during the period from 1995 to 2002. Of course, not all of the total liabilities in the sample enterprises correspond to loans from the banks. But even assuming that 60% of the total liabilities in the sample are related to various bank loans, the statistical analysis in the paper would provide in-depth study on the quality of about 27% to 29% of China's total loans. In summary, although the members of sample enterprises are changing each year but they as a whole forms a stable club of China's industrial elite enterprises. The performance of this elite group of enterprises are much more representative of the performance of the Chinese industrial economy than, for example, the performance of the listed companies in China or any small sample study of Chinese enterprises occasionally conducted by the researchers. Given the growing importance of China's industrial sector for both the domestic and global

economy, our analysis in this paper fills a crucial vacuum in understanding the dynamics of China's industrial reform and development.

Table 1.1, 1.2, and 1.3 shows the distribution of the total liabilities for the sample enterprises by ownership, industry, and region respectively. The objective of this paper is to find out how much of these debts are located in profit-making and loss-making enterprises and then to calculate the amount and ratio of NPDs. There are two underlying forces affecting the NPD ratios: the shifting distribution of debts across enterprise groups with different profitability and the changing profitability of each group.

Let's take a look at Table 1.1, which shows the distribution of total liabilities (or total debts) across ownership types. The share of total debts by SOEs fell sharply from 76.4% in 1995 to 48.2% in 2002, to the benefits of domestic mixed ownership corporations and private enterprises. The total debts for SOEs increased from RMB 2.5 trillion in 1995 to RMB 3.2 trillion in 1998 just before the Asian financial crisis, and then fell to RMB 2.8 trillion in 2002. The total debts for collectives followed the same pattern of SOEs, rising from RMB 227 billion in 1995 to RMB 287 billion in 1998 and then falling to RMB 219 billion in 2002. The shifting of debts towards private, mixed, foreign, or overseas Chinese enterprises has been steady and rapid throughout the period from 1995 to 2002 without any interruption by the Asian financial crisis in 1998-1999. For the eight years from 1995 to 2002, the total debts in the sample enterprises increased RMB 2,436 billion. Among the net increase, only RMB 246 billion ended in the SOEs, RMB 1,411 billion went to mixed ownership enterprises, RMB 467 billion to foreign enterprises, RMB95 billion to private enterprises. The drastic changes in the distribution of total debts are strong evidences showing rapid but quiet privatization and opening up for the most dynamic part of

China's industrial sector. In the next section, we will show that the redistribution of total debts from SOEs towards the better performing NSEs contributed to the larger part of the observed fall in average NPD ratios for the sample enterprises.

How financial resources are allocated among the Chinese industrial enterprises during the period 1995-2002, which can be characterized by high growth and steady reform? Which industries and regions are getting more financial resources for their elite industrial enterprises? Table 1.2 and 1.3 provides the answer. The two tables give us detailed information about the credit allocation among China's large and medium-sized industrial enterprises and illustrate the changing landscape of the Chinese enterprise financing. In Table 1.2 and 1.3 the total debts for each industry or region are sorted by their amount in 2002 to make it easy to look for the winners and losers. The last two columns show the amount of change and growth rate for total debts during the period 1995-2002.

As shown in Table 1.2, the top 5 industries in 2002 ranked by the level of their total debts are:

1. Electric Power, Steam and Hot Water
2. Transport Equipment Manufacturing
3. Smelting & Pressing of Ferrous Metals
4. Electronic and Telecom Equipment
5. Raw Chemical Materials and Chemical

The top five industries together attracted RMB2.692 trillion of debts or 47% of the total for the whole sample. The net gains of debts for the top five industries during 1995-2002 amounted to RMB 1.465 trillion, or 60% of the gains by the whole sample. China's financial risks would be heavily influenced by the performance of the above five sectors.

From the last column of Table 1.2, the top 5 industries ranked by the growth of their total debts during 1995-2002 can be identified as the following:

1. Tap Water Production and Supply
2. Electric Power, Steam and Hot Water
3. Electronic and Telecom Equipment
4. Papermaking and Paper Products
5. Gas Production and Supply

Clearly the above leading industries, which are attracting investment in the last decade, are largely related to industrial infrastructure, intermediate inputs, raw materials, production equipments and utilities. The rapid development of these industries, would lay a solid foundation for China's further industrialization. In this sense, China's enterprise finance looks consistent with the market forces. Of course, a risk-based regulation strategy would require extra attentions to be paid to these sectors with heavy concentration in enterprise financing. As we will see in the next section, some of the above sectors with rapid growth in enterprise debts do have high NPD ratios, especially in the SOE dominated utilities sector.

From Table 1.3 we can see the top 5 regions ranked by the level of their total enterprise debts in 2002 are Guangdong, Jiangsu, Shandong, Shanghai, and Liaoning. These regions are clearly becoming China's new industrial centers.

In the next section, we will show how much of the total debts shown in Table 1.1 to 1.3 is located in loss-making enterprises. The profitability of the enterprises becomes the crucial variable for our study. The reported profits however have a number of problems. First, it is hard to check the consistence of the reported profits with other financial variables of the enterprises due to the complicated accounting regulations. In another word, we do not know how the reported profits are calculated from other financial variables reported in the NBS survey. Second, it is widely reported that enterprises may manage their profit numbers legitimately or not for many purposes including legal or illegal tax evasion. Hence, it seems useful to develop an alternative measure of profitability based on a consistent set of financial

variables available from the NBS survey. Since the main purpose of the NBS survey is to calculate the value added of the industrial enterprises, it is possible to develop a measure of profitability or potential profitability based on the reconstructed components of enterprise's value added.

We use the following variables available from the NBS survey to define the imputed profitability of the sample enterprises:

VA: value added including value added taxes and financial changes;
W: wage and other employee benefits.
FC: financial charges, mainly interest payments.
D: current depreciations;
T: all tax payments including value added taxes;
TA: total assets

We classify enterprises into eight profitability groups:

[-4]: if VA <= 0;
[-3]: if VA–W <= 0 AND VA > 0;
[-2]: if VA-W-FC <= 0 AND VA-W > 0;
[-1]: if VA-W-FC-D <= 0 AND VA-W-FC > 0;
[+1]: if VA-W-FC-D-T <= 0 AND VA-W-FC-D > 0;
[+2]: if VA-W-FC-D-T > 0 AND (VA-W-FC-D-T)/TA <= 5%
[+3]: if (VA-W-FC-D-T)/TA > 5% AND (VA-W-FC-D-T)/TA<= 15%;
[+4]: if (VA-W-FC-D-T)/TA > 15%;

Table 2.1 shows the number of enterprises in each of the eight profitability groups over the period from 1995 to 2002. This imputed profitability by eight groups would allow us to separate the non-performing debts into more disaggregated groups by the degrees of loss-making. The Chinese banks are in the process of changing their loan classification from four categories (normal, overdue, doubtful, and bad) into the international standard of five categories (normal, special mention, substandard, doubtful, and loss). Unlike the classification of loans, the profitability classification here reveals the underlying economic conditions, for example:

- Enterprises in profitability group [-4] create negative value added. They should be closed right away according to economic principles. The quality of their debts is worst among the eight groups by profitability.
- Enterprises in group [-3] have positive value added but cannot pay all of their wage bills. In economics, they cannot even cover their variable costs. They should also be closed as soon as possible to avoid incurring new losses. The quality of their debts would get worse every day.
- Enterprises in group [-2] can pay their wage bills but cannot pay all of their financial changes. The quality of their debts is poor but since the investment is sunk it may have reasons to continue operation in the short run, waiting for turnaround after reorganization.
- Enterprises in group [-1] can pay their wage bills and financial charges but cannot cover all of their depreciation charges. The quality of their debts will fall as capital is depleted.

However due to space limitation, we will leave the more detailed analysis on NPDs based on the above profitability classifications for a separate paper. For this paper, we will focus on the big picture first and classify enterprises in the first four groups as loss-making and the last four groups as profit-making by imputed profitability.

Table 2.2 shows the number of enterprises making or losing profits based on both reported and imputed profits over the period from 1995 to 2002. The number of loss-making enterprises by imputed profitability was quite stable at about 8000 or 34% to 35% during 1995-1998 and then fell rapidly afterward to 4952 or 22.3% in 2002. The number of loss-making enterprises by reported profitability was 6937 or 30.8% in 1995 and rose sharply to 8987 or 40.3% in 1998 and then dropped to 6295

or 28.3% in 2002. In the next section, we will use both the imputed and reported profitability to estimate the amount and ratio of NPDs using the concept and measurement method developed in this section. Although the two profitability measurements are quite different in concept and measurement, both are useful for assessing the quality of enterprises debts. The imputed profitability is more useful for comparing enterprise performance across groups since it is based on a consistent set of reported financial variables but it is different from the actually reported profitability. The imputed profits could be larger than the reported profits for a number of reasons: first, since some of the value added may not turn into actual profits when the output is not sold or is still in inventory. Second, it is likely that reported profits may be lower than the imputed profits due to legal or illegal tax evasions or profit hiding. We will examine this complicated issue in a separate paper.

3. Statistics of Non-Performing Debts

Using the method developed in the last section, this section reports the main results on NPD statistics for the whole sample as well as by ownership, industry and region. Table 3.1 shows the amount of NPD as well as NPD ratio for the whole sample during the period from 1995 to 2002. There are two sets of NPD statistics in the table: the upper part is derived from the imputed profits and the lower part from the reported profits. In Table 3.1 the amount and the ratio of NPD are calculated for three categories of debts separately: total liabilities, long-term liabilities, and short-term liabilities. They are quite similar in size and trend with NPD ratio for short-term liabilities declining slightly faster than for long-term liabilities.

According to the imputed profitability, the NPD ratio for the whole sample was quite stable around 27% to 30% during 1995-1999 afterwards to only 18.4% in

2002 with the amount of NPDs at about RMB 1 trillion. According to the reported profitability, the NPD ratio for the whole sample was at 24.1% in 1995 and rose to 34.3% in 1998 and then fell to 22.9% with the amount of NPDs at about RMB 1.3 trillion in 2002. According to the CBRC, China's NPL ratio fell in rent years to 15.19% with the amount of NPLs at RMB 2.4 trillion by the end of 2003. Given the different definitions between NPLs and NPDs, the results we have here for NPD statistics look quite consistent with the CBRC statistics for NPLs. In the next section, we will examine further the trend of NPD ratios for the whole sample.

Table 3.2 and 3.3 compares the NPD statistics for different types of enterprises by ownership derived from both the imputed and reported profitability. The two tables show the NPD ratios vary significantly across types of enterprises by ownership with the SOEs have much higher NPD ratios than NSEs:

In 2002, the NPD ratio for the SOEs was 25.4% by imputed profitability and 25.8% by reported profitability. The NPD ratio for the private enterprises was 7.4% by imputed profitability and 15.8% by reported profitability. The NPD ratio for the domestic mixed ownership enterprises was 10.8% by imputed profitability and 20.2% by reported profitability.

From these NPD statistics in Table 3.2 and 3.3, it is possible to decompose the fall of average NPD ratio for the whole sample into two parts: the one due to improvement of NPD ratios in each type of the enterprises and the other part due to the redistribution of debts from SOEs to the better performing NSEs.

Let's assuming R^t_i is NPD ratio in year t for group i of enterprises and S^t_i is the share of debts by group i, then the NPD ratio for the whole sample in year t can be calculated from the following equation:

$$R^t = \sum_i R^t_i * S^t_i;$$

where i = private, collective, mixed, foreign, HK-M-Taiwan, SOE;

The change of NPD for the whole sample from 1995 to 2002 can be presented equivalently in the following formats:

$$R^{2002} - R^{1995}$$

$$= \sum_i R^{2002}_i * S^{2002}_i - \sum_i R^{1995}_i * S^{1995}_i$$

$$= \sum_i 0.5*(R^{2002}_i + R^{1995}_i)*(S^{2002}_i - S^{1995}_i) + \sum_i 0.5*(R^{2002}_i - R^{1995}_i)*(S^{1995}_i + S^{2002}_i);$$

The first term in the above equation is the first component of the change in NPD ratio for the whole sample during 1995-2002 that can be attributed to the shift of the total liabilities across ownership groups while holding the individual ownership group's NPD ratio at their average level for 1995 and 2002. Using statistics from Table 1.1, 3.2 and 3.2, this first component is -3.86% for imputed profitability method and -2.33% for the reported profitability method.

The second term is the second component of change in NPD ratio for the whole sample during 1995-2002 that can be attributed to the fall in individual ownership group's NPD ratio while holding the distribution of total liabilities across ownership groups at their average level for 1995 and 2002. This second component is -4.74% for the imputed profitability method and 1.13% for the profitability method.

Hence, according to the imputed profitability method, the NPD ratio for the whole sample fell from 27.8% in 1995 to 18.4% in 2002, a drop of 9.8%. Out of this 9.8%, 3.86% can be attributed to shift of financial resources from SOEs to the better performing NSEs, which have lower NPD ratios than SOEs.

According to the reported profitability method, the NPD ratio for the whole sample fell only slight from 24.1% in 1995 to 22.9% in 2002, a drop of only 1.21%. The decomposing of this 1.21% shows that the shift of financial resources from SOEs to the better performing NSEs led to 2.33% drop in the NPD ratio for the whole

sample while the changes in the NPD ratios for individual ownership groups have led to an increase of 1.13% in the NPD ratio for the whole sample.

Clearly the fall of NPD ratio is more significant according for the imputed profitability than for the reported profitability. As pointed out before, we are not clear how the reported profits are calculated because of the large variations in accounting and profit-reporting practices across types of enterprises, but we know exactly how the imputed profits are calculated from the financial variables that are used for measuring GDP. We think both measures are useful. The NPD statistics derived from the imputed profitability can be used for comparing the underlying performance of different groups of enterprises while the NPD statistics from the reported profitability reflects better the actually outcomes the creditors are going to face when they deal with the enterprises.

Table 4.1 to 4.4 contains NPD statistics by industry during 1995-2002. Table 4.1 and 4.2 are derived from the imputed profitability while Table 4.3 and 4.4 from reported profitability. Table 5.1 to 5.4 contains NPD statistics by industry during 1995-2002. Table 5.1 and 5.2 are derived from the imputed profitability while Table 5.3 and 5.4 from reported profitability. All the above eight tables are sorted by the last column for 2002 so that readers can see easily the best and worse performers in the quality of enterprise debts. The information here gives the big picture on the quality of enterprise debts across industry and region and can be used by the policy-makers, the banks, the investors, and the enterprises as a benchmark to check the performance of their own debt portfolios. This information is a public good and contributes to the more scientific management of the debt risks in China. The next section tries to summarize the key contents of the detailed information in these tables and makes them easier to use by the policy-makers and practitioners.

4. Patterns of Non-Performing Debts

As pointed out in previous sections, the two sets of NPD statistics estimated in this paper are useful as benchmarks for policy-makers and practitioners. Bankers from Shanghai and Guangdong may want to know the NPD statistics in their regions. Officials in charge of utilities may also want to know how bad that sector's enterprise debts are compared to other industries. Applying simple regression method to the disaggregated NPD ratios, we can summarize the variability in NPD ratios from two dimensions: one is the declining trend of NPD ratio and the other is the gaps in NPD ratios across the ownership, industry and region. These patterns are useful for illustrating the overall quality of enterprise debts in China as well as for informed policy debates.

Table 6.1 to 6.3 shows the results of six regressions using group NPD ratios reported in the six tables respectively (e.g. Table 3.2, 3.3, 4.2, 4.4, 5.2, and 5.4). In each of the six regressions, the independent variables include a time trend (year) and a categorical variable (ownership, industry, or region respectively). Each categorical variable includes an additional value of "the whole sample" to denote the NPD ratio for the whole sample. The regression equations can be written as the following:

NPD ratio = f(year, categorical variable);

We use weight regressions to discount the impact of NPD ratios in the early years (see weights in the footnote of Table 6.1, 6.2 and 6.3). The regression coefficient for the time trend variable (year) would indicate how fast the NPD ratio would fall every year based on the variability of the NPD ratios reported for each group in the relevant tables. In principle, the declining trend of NPD ratios for all the groups is related to the improvement of general market environment of the Chinese economy due to

reform and opening. The regression coefficients for the categorical variable would indicate the average gap between the NPD ratio of that particular category and the NPD ratio of the base category (which is indicated by a zero value for the coefficient and a blank value for t statistics in the tables) after taking out the influence of the declining trend in NPD ratio. The negative sign means "lower than" the NPD ratio of the base category.

For example Table 6.1 shows that based on NPD ratios estimated from the imputed profitability and reported in Table 3.2 on average the NPD ratios for a particular group is likely to decline by 1.5% each year. The NPD ratio for the private enterprises is likely to be 21.3% lower than that for SOEs. The NPD ratio for the whole sample is likely to be 12.4% lower than that for SOEs.

Regressions in Table 6.1, 6.2, and 6.3 can be used to make rough predictions for NPD ratios of a particular group in the future. But these rough predictions are only based on the pattern of NPD ratios during 1995-2002. Figure 1 and 2 shows the actual and predicted value of NPD ratios using the regression coefficients in Table 6.1 to 6.3. when the categorical variable is set to the whole sample. Figure 1 is based on the imputed profitability and shows a much faster rate of decline in NPD ratios than Figure 2, which is based on reported profitability.

A more sophisticated method for assessing the likely NPD ratios in the future years for the whole sample is to build a few likely scenarios based on alternative assumptions on the possible NPD ratios for individual groups and the possible distribution of total liabilities. Table 6.4 outlines nine scenarios for the NPD ratios for the whole sample by the year 2007 by providing specific alternative assumptions about possible NPD ratios for each group of enterprises and about possible distribution of total liabilities across groups. These simulated scenarios could

facilitate policy debates by showing the magnitude of reforms necessary to achieve the objectives. For example, Table 6.4 shows that to lower the overall NPD ratio to 14.7% by the year 2007, it is necessary for individual groups to achieve NPD ratios in the optimistic case (e.g. 2002 NPD ratios estimated from imputed profitability) and for the distribution of total liabilities also to achieve the optimistic case where the SOE sector share of total liabilities falls to 20.2%. The nine scenarios in Table 6.4 are built for illustration purpose. The alternative assumptions are subjective and debatable but are all based on the patterns of NPD statistics estimated in this paper.

5. Explaining Profitability

In the previous section, we have estimated NPD ratios for individual groups of enterprises by ownership, industry, and region. We found that the SOEs have much higher NPD ratios than the NSEs as well as differences in NPDs across industry and region. The NPD statistics for each group of enterprises reflect the total effects from all factors that may cause non-performing debts. For example, a major factor contributing to high NPD ratio for the SOEs may be the fact that a lot of enterprises in the utilities industry are SOEs and the whole utilities industry is not profitable because of heavy price regulations by the government. In this case, the high NPD for the group of SOEs actually reflected both the ownership and industry risks. The purpose of this section is to use regression analysis to isolate different sources of risks related to the quality of enterprise debts. Since we have classified enterprise debts by their profitability, what we need to do is to explain why some enterprises are making profits or why some enterprises have higher returns on their assets.

Table 7.1 gives the summary statistics for key variables used in the profitability regressions. Table 7.2 shows the median of the key regression variables,

which would give a better sense about the size of the key variables across ownership types and over time.

Table 7.3 reports the results of four regressions: two logistic regressions explaining the imputed and reported profitability and two linear regressions explaining the imputed and reported return on total assets. The explanatory variables for the four regressions are the same, including the log(capital-labor ratio), asset-liability ratio, log(employees), market share, industry concentration, and dummy variables for ownership, year, industry, and region. The coefficients and their standard error indicate the size and the statistical significance of the impact on the profitability by the explanatory variables.

Some common patterns emerge in all of the four regressions:

- The asset-liability ratio has significantly negative impact on profitability;
- Market share has positive impact on profitability;
- State ownership has negative impact on profitability;
- Profitability improves significantly during 2000-2002;

It should be noted that the above are independent impacts by each explanatory variable after controlling for the impacts of other explanatory variables, including the impact of industry and region variables.

The impacts of ownership on profitability revealed by each of the four regressions are the following:

- In the logistic regression on the imputed profitability, as compared to the private enterprises, the odds ratio for collective, mixed, foreign, HK-M-Taiwan, and SOEs to be profitable should be multiplied by 0.637, 0.586, 0.466, 0.469, and 0.291 respectively.

- In the logistic regression on the reported profitability, as compared to the private enterprises, the odds ratio for collective, mixed, foreign, HK-M-Taiwan, and SOEs to be profitable should be multiplied by 0.806, 0.910, 0.391, 0.518, and 0.557 respectively.
- In the linear regression on the imputed profitability, the return on total assets by the private, collective, mixed, foreign, HK-M-Taiwan enterprises will be 10.6%, 7%, 4.7%, 6.5%, and 5.3% higher than the SOEs.
- In the linear regression on the reported profitability, the return on total assets by the private, collective, mixed, foreign, HK-M-Taiwan enterprises will be 2.9%, 2.2%, 1.7%, 1.7%, and 1.5% higher than the SOEs.

Table 7.4 and 7.5 use the industry and region dummies in the four profitability regressions to construct the pure industry profitability index and the pure region profitability index. These tables can be used as benchmarks for assessing the pure industry and region risks of enterprise debts in China. They summarize the independent impacts of industry and location on the quality of industrial enterprise debts averaged over 1995-2002.

PI-1, PI-2, PI-5, PR-1, PR-2, and PR-5 are derived from the industry or region dummies in the logistic regressions but normalized by the sample average. As compared to the sample average, the odds ratio for specific industry or region to be profitable should be multiplied by the index value. For example, the index value of PI-5 in Table 7.4 is 5.607 for tobacco industry. The odds ratio for tobacco industry to be profitable, as compared to the average profitability of all industries, should be multiplied by 5.607, when other factors influencing profitability are held constant.

PI-3, PI-4, PI-3, PR-4, PR-6, and PR-6 are derived from the industry or region dummies in the linear regressions but are also normalized by first subtracting the

average return of all industries or regions and then adding 1. This makes index value equal to 1 for the average of all industries or regions. The index value minus 1 is the additional return a specific industry or region has over the average return on total assets. For example, the index value of PI-6 in Table 7.4 is 1.166 for tobacco industry. This means that tobacco industry's return on total assets is likely to be 16.5% higher than the average return on total assets for all industries.

Hence, Table 7.4 and 7.5 helps us to find out which industry and region are more profitable for the large and medium-sized industrial enterprises when the influences of other factors such as types of ownership are taken way. The two tables are sorted by PI-5 and PR-5 from high to low profitability. The top five industries by pure industry profitability are:

1. Tobacco Processing
2. Petroleum and Natural Gas Extraction
3. Electric Power, Steam and Hot Water
4. Beverage Production
5. Medical and Pharmaceutical Products

The top five regions by pure region profitability are:

1. Shandong
2. Jiangsu
3. Hebei
4. Zhejiang
5. Henan

The profitability regressions in Table 7.3 could also be used to assess the profitability risks of a particular type of enterprises if we know the value of the explanatory variable for that enterprise. The predicted value from the logistic regressions is the probability of making profits. Of course, the prediction using the regressions equation only helps to assess non-enterprise-specific risks that are related to the explanatory variables in the regressions. In the real world and for a specific enterprise, the enterprise-specific risks are clearly most important.

6. Implications for Banking Reform

This paper investigates empirically the quality of enterprise debts in China. It uncovered large amount of independent, consistent and statistically significant micro-level evidences which shows that the quality of enterprise debts in China have indeed improved during the period 1995-2002, especially after 1998. These evidences look much more convincing than the macro statistics announced by China's financial authorities due to the transparency and scientific methods used in the research.

The fall in NPD ratios is brought about by the shift of financial resources from SOEs to NSEs as well as by the improvement in the profitability of SOEs and NSEs.

Both reforms on corporate governance and the timing of business cycles could have contributed to the recent improvement in enterprise profitability in China and the fall in NPD ratios. But the benefits of business cycles timing and reform dividends could be uncertain in the future.

China can however continue to benefit from the shift of financial resources from the SOEs to better performing NSEs since the gaps in performance between the two are still very big.

The gaps in profitability across industry and region in China are also large, showing the need for better risk management and more efficient allocation of financial resources. The information and analysis in this paper could contribute to better assessment of various risks relating to ownership, industry, and region.

The rising share by NSEs of financial resources and the declining NPD ratio for all types of enterprises provide excellent opportunities for pushing banking reforms in China now. If the banks can establish good corporate governance and risk management, there seem enough good NSEs to lend to.

However, most of the major banks in China are still state-owned. Given the strong evidences that SOEs are performing much worse than NSEs, it seems that developing good private banks or privatizing the state-owned banks (SOBs) should be the priority for banking reform.

If China fails in the development of private banks, there could be a high risk that China may continue to have high NPL ratio even when its NPD ratio is falling due to privatization of enterprises and enterprise debts. This is because SOBs could create NPLs independent of good performance of China's enterprise sector.

Appendix 1: Data Cleaning

The NBS survey covers more than 20,000 large and medium-sized industrial enterprises in China. There are some unusable observations due to incomplete data reporting or small enterprises which were classified as large and medium-sized historically based on their design production capacity. The classification standard for the size of industrial enterprises was first issued in April 1988 by a number of government agencies including the State Planning Commission, National Bureau of Statistics, Ministry of Finance, Ministry of Labor, and State Economic Commission. It includes detailed specifications based on the measurement of the output quantity or capacity in technical quantity terms, instead of in value terms. The standard is clearly a legacy of the centrally planned economy and is phasing out recently. It now only applies to state-owned industrial enterprises. For the private enterprises, the National Bureau of Statistics is using the sales as the unique variable in determining size of the enterprises.

In this study, observations satisfying one of the flowing screening conditions are regarded as unusable and deleted from the usable sample.

1. Net value of fixed assets < RMB100,000;
2. Intermediate inputs < RMB100,000;
3. Number of employees < 30;
4. Gross value of industrial inputs at current price < RMB100,000;
5. Sales < RMB100,000;
6. Total assets < RMB100,000;
7. Total assets – liquid assets < 0;
8. Total assets – gross fixed assets < 0;
9. Total assets - net value of fixed assets < 0;
10. Accumulated depreciation – current depreciation < 0;
11. MISSING data for total assets, number of employees, gross value of industrial output at current price, net value of fixed assets, or sales;

After deleting the unusable observations, only about 5% or less of the sample enterprises have sales values less than RMB 5 million. Table A.1, A.2, and A.3 show

the distribution of usable and unusable observations in the sample by ownership, industry and region. Since the unusable observations are evenly distributed across ownership, industry, and region, we believe excluding them from the usable sample would not create much bias in our analysis.

Table A.4 shows the summary statistics for key size variables for the sample, including sales, output, assets, liabilities, labor, and value added. Table A.5 shows the same set of size variables at their selected percentiles. Table A.6 examines the weight of sample within the context of the Chinese economy. Clearly the sample represents an important part of the Chinese economy and this makes statistical analysis on the sample important and valuable for both policy makers and practitioners.

Appendix 2: List of industry code and the full industry name:

06 Coal Mining and Dressing
07 Petroleum and Natural Gas Extraction
08 Ferrous Metals Mining and Dressing
09 Nonferrous Metals Mining and Dressing
10 Nonmetal Minerals Mining and Dressing
12 Logging and Transport of Timber & Bamboo
13 Food Processing
14 Food Production
15 Beverage Production
16 Tobacco Processing
17 Textile Industry
18 Garments and Other Fiber Products
19 Leather, Furs, Down and Related Products
20 Timber, Bamboo, Cane, Palm Fiber & Straw
21 Furniture Manufacturing
22 Papermaking and Paper Products
23 Printing and Record Medium Reproduction
24 Cultural, Educational and Sports Goods
25 Petroleum Processing and Coking
26 Raw Chemical Materials and Chemical
27 Medical and Pharmaceutical Products
28 Chemical Fiber
29 Rubber Products
30 Plastic Products
31 Nonmetal Mineral Products
32 Smelting & Pressing of Ferrous Metals
33 Smelting & Pressing of Nonferrous Metals
34 Metal Products
35 Ordinary Machinery Manufacturing
36 Special Purposes Equipment Manufacturing
37 Transport Equipment Manufacturing
40 Electric Equipment and Machinery
41 Electronic and Telecom Equipment
42 Instruments, Cultural & Office Machinery
43 Other Manufacturing
44 Electric Power, Steam and Hot Water
45 Gas Production and Supply
46 Tap Water Production and Supply

Table 6.4 Scenarios for NPD Ratio of the Whole Sample by the Year 2007

	Alternative Assumptions about Distribution of Total Liabilities		Pessimistic Case: Two Year Slower than Predicted by the Trend	Likely Case: As Predicted by the Trend	Optimistic Case: Two Year Faster than Predicted by the Trend
Alternative Assumptions about the Value of NPD Ratios	private		2.9%	3.7%	4.5%
	collective		2.6%	1.8%	1.0%
	mixed		38.0%	44.2%	50.4%
	foreign		13.5%	15.3%	17.1%
	HK-M-Taiwan		7.7%	8.3%	8.9%
	state-owned		36.2%	28.2%	20.2%
Optimistic Case: 2002 NPD Ratios Estimated from Imputed Profitability (%)	private	7.4%	**16.8%**	**15.8%**	**14.7%**
	collective	10.0%			
	mixed	10.8%			
	foreign	15.2%			
	HK-M-Taiwan	12.6%			
	state-owned	25.4%			
	weighted average for all	18.4%			
Likely Case: 2002 Average NPD Ratio (average over NPD statistics from both imputed and reported profitability)	private	11.6%	**19.6%**	**18.9%**	**18.3%**
	collective	14.6%			
	mixed	15.5%			
	foreign	18.8%			
	HK-M-Taiwan	15.4%			
	state-owned	25.6%			
	weighted average for all	20.6%			
Pesimistic Case: 2002 NPD Ratio Estimated from Reported Profitability (%)	private	15.8%	**22.4%**	**22.1%**	**21.8%**
	collective	19.2%			
	mixed	20.2%			
	foreign	22.4%			
	HK-M-Taiwan	18.2%			
	state-owned	25.8%			
	weighted average for all	22.9%

a. The indices in this table are derived from the coefficients of industry dummies in the profitability regressions reported in Table 7.3. For easy comparison, each profitability index is normalized by the sample average. Index that is greater than 1 would indicate profitability better than the sample average. The 6 index values are sorted by PI-5.
